Urinalysis

Microalbumin, Urine	78
Dipstick	78
Quantitative	79
Creatinine, Urine	78
Dipstick	78
Quantitative	79
Urinalysis Dipstick	81
Specific Gravity	81
pH	82
Protein.....	83
Glucose.....	84
Ketones.....	85
Bilirubin	86
Urobilinogen.....	87
Blood or Hemoglobin.....	88
Leukocyte Esterase.....	89
Nitrite.....	90
Microalbumin (Dipstick Only).....	91
Urine hCG	92
Fecal Occult Blood	93
KOH Skin Preparation	79
Urine Sediment Identification	94
Provider-Performed Microscopy (PPM)	
Provider-Performed Microscopy (PPM)	97

EVALUATION CRITERIA

The evaluation criteria used in the MLE Program is in accordance with the Clinical Laboratory Improvement Amendments of 1988 (CLIA '88) federal requirements for proficiency testing. The criteria are included below.

Qualitative

For qualitative procedures, evaluation is based on participant or referee consensus. If participant consensus is not reached, CMS requirements call for grading by referee consensus. A minimum percentage of participants or referee laboratories must receive a passing score or the challenge is not evaluated due to lack of consensus. These percentages are listed below.

ABO Group	95% Participant or 100% Referee Consensus
Antibody Identification	95% Consensus
Blood Cell Identification	80% Consensus
Compatibility Testing	95% Participant or 100% Referee Consensus
Creatinine (Semi-Quantitative)	80% Consensus
Crystal Identification	80% Consensus
Fecal Occult Blood	80% Consensus
KOH Skin Preparation	80% Consensus
Microalbumin (Semi-Quantitative)	80% Consensus
Provider-Performed Microscopy	80% Consensus
Rh Factor (D Type)	95% Participant or 100% Referee Consensus
Unexpected Antibody Detection	95% Consensus
Urine Dipstick	80% Consensus
Urine hCG	80% Consensus
Urine Sediment Identification	80% Consensus

Quantitative

For quantitative procedures, a mean and standard deviation (SD) are calculated for each peer group consisting of 10 or more laboratories except for Coagulation (CG Specimens) which consist of peer groups of 5 or more laboratories. Acceptable performance is established on a target value \pm the intervals below. An explanation on how to calculate the range of acceptability based upon these limits is also provided in your MLE Program Guide on page 37 under the heading "Acceptable Ranges for Quantitative Results."

Activated Partial Thromboplastin Time	$\pm 15\%$
Automated Differential	± 3 SD
Body Fluid - Red Cell Count	± 2 SD
Body Fluid - White Cell Count	± 2 SD
Creatinine, Urine (Quantitative)	$\pm 17\%$
Fibrinogen	$\pm 20\%$
Glucose, Whole Blood – HemoCue	± 6 mg/dL or $\pm 20\%^*$
Hematocrit	$\pm 6\%$
Hematocrit, Waived	$\pm 6\%$ or ± 2 SD*
Hemoglobin	$\pm 7\%$
Hemoglobin, Waived	$\pm 7\%$ or ± 2 SD*
International Normalized Ratio (INR)	$\pm 15\%$
Microalbumin (Quantitative)	$\pm 30\%$
Platelet Count	$\pm 25\%$
Prothrombin Time	$\pm 15\%$
Red Blood Cell Count	$\pm 6\%$
Reticulocyte Count	$\pm 30\%$ or ± 2 SD*
Sedimentation Rate	± 3 SD
Specific Gravity	± 0.010
White Blood Cell Count	$\pm 15\%$

*Whichever is greater

2022 M2
BLOOD CELL IDENTIFICATION
Specimens BC-7 through BC-12

CASE HISTORY:

A 59-year-old male presented to his family physician with recent onset of headaches, body aches, fever, chills, and sweating during the night. He returned 2 weeks ago from a month-long trip overseas to Angola. The patient stated that during his time in Africa he generally felt well and did not take any medication. He stayed in the homes of his relatives and consumed the local food and water. The patient's electronic medical record showed that at his last visit in 2020 he had a positive anti-HCV screening test and declined antiviral treatment for chronic hepatitis C.

A CBC was performed, and results appear below.

.
.

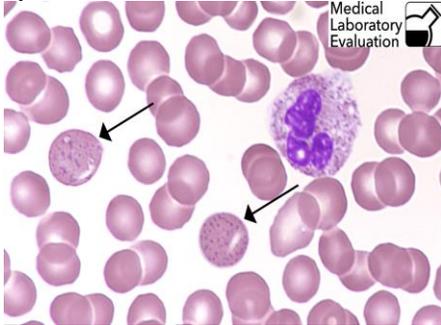

Test	Results	Reference Range
WBC	2.6 x 10 ⁹ /L	4.5 - 11.5 x 10 ⁹ /L
RBC	3.5 x 10 ¹² /L	4.6 - 6.0 x 10 ¹² /L
HGB	10.1 g/dL	14.0 - 18.0 g/dL
HCT	33 %	40 - 54 %
PLT	87 x 10 ⁹ /L	150 - 450 x 10 ⁹ /L
MCV	94 fL	80 - 94 fL
MCH	29 pg	27 - 32 pg
MCHC	31 g/dL	32 - 36 g/dL
RDW	16.5 %	11.5 - 14.5 %

This patient was diagnosed with malaria. Malaria is a potentially fatal acute febrile illness caused by a bloodborne protozoan parasite. Malaria is common in tropical and subtropical regions, such as sub-Saharan Africa and South Asia, which are endemic for the mosquito that transmits it. When an infected female *Anopheles* mosquito bites a human, it injects the parasites. The parasites travel to the liver and reproduce in hepatic cells until those cells erupt, releasing parasites into the blood stream. They invade circulating red blood cells, where they feed, grow, and multiply. The infected red cells rupture, then emerging parasites spread to other red cells, repeating the cycle, resulting in hemolysis and anemia. In non-immune individuals, symptoms appear weeks to months after the infective mosquito bite. Early symptoms of malaria can be mild and difficult to diagnose. Nearly all patients with malaria present with headache. Immune individuals may present with mild anemia or they may be completely asymptomatic. Splenomegaly may be present. Common symptoms include cyclical fever and chills, malaise, muscle aches, nausea, weakness, vomiting and diarrhea. Since these symptoms are non-specific, malaria should be suspected in all febrile travelers, regardless of clinical presentation. Imported malaria cases will continue to be a worldwide problem in the future as the climate changes and the mobility of travelers and migrants increases.

Common laboratory findings in malaria patients include normochromic-normocytic anemia, thrombocytopenia, and elevated LDH, bilirubin, and creatinine. Testing for malaria includes examination of thick and thin peripheral blood smears. Thick smears are 20 times more sensitive than thin smears in detecting the presence of malaria parasites, but one negative smear does not rule out malaria as the diagnosis. Several more smears should be examined over a 36-hour period. The thick smear is a screening test in which the parasites can be detected more easily. The thin smear is used for species identification and quantification of parasitemia (%) calculated based on the number of infected RBCs observed. In the U.S., only about 1500 cases of malaria are diagnosed and reported each year, therefore most laboratorians in the U.S. do not perform this testing regularly. However, healthcare providers need the results within hours in order to appropriately treat a patient with malaria, so the microscopic exam should always be considered a "STAT" procedure, collected and performed immediately. The test should not be saved for the most qualified staff to perform or sent out to a reference laboratory that takes days to report the results.

BLOOD CELL IDENTIFICATION

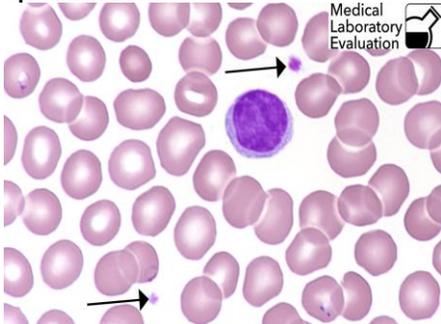

Specimen BC-7

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Basophilic stippling	123	94.62%	Acceptable
Immature/abnormal cell – refer	3	2.31%	Acceptable

The arrows in this photograph point to erythrocytes with **basophilic stippling**. These young red blood cells still contain some residual RNA aggregated into small granular clumps that stain dark blue-purple. The clumps of RNA are evenly distributed throughout the cell, and may appear fine (small) or coarse (large). Basophilic stippling is associated with anemia, increased RBC production, defective heme synthesis, thalassemia, and lead poisoning. Reticulocytes are similar, but must be identified using a supravital stain such as New Methylene Blue. To view another photo of basophilic stippling, see 2020 M3 Specimen BC-15. To view a photo of reticulocytes, see 2015 M2 Specimen BC-12.

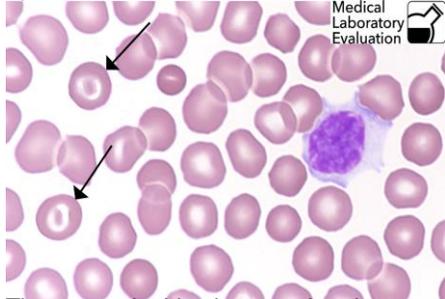

Specimen BC-8

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Platelet, normal	128	98.46%	Acceptable

The arrows in this photograph point to **normal platelets**. Platelets generally have a central area packed with red to violet colored granules, and a clear blue area that surrounds the granules. Platelets are round to elliptical in shape and less than half the size of a normal red blood cell. Normal platelets measure 2-4 microns, while mature erythrocytes measure 6-8 microns. To view another photo of normal platelets, see 2020 M2 Specimen BC-9.

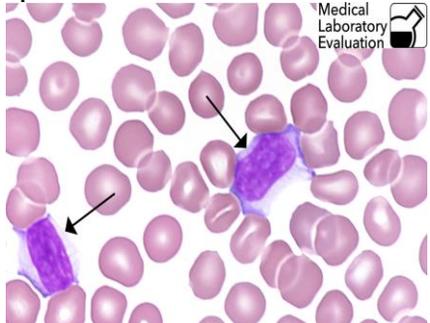

Specimen BC-9

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Target cell	128	98.46%	Acceptable

The arrows in this photograph point to **target cells**. The dark spot in the center gives the cell a bulls-eye appearance. In three dimensions, these red blood cells are bell-shaped rather than the normal biconcave disk shape. This is either due to decreased hemoglobin, excess membrane, or an abnormal hemoglobin. Target cells are frequently seen in liver disease, hemoglobinopathies, iron deficiency, and hyposplenias. To view another photo of target cells, see 2018 M2 Specimen BC-7.

Specimen BC-10

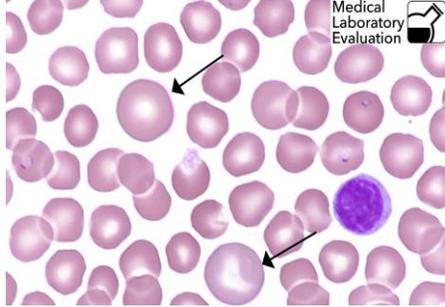

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Lymphocyte, reactive	84	64.62%	Acceptable
Immature/abnormal cell – refer	45	34.62%	Acceptable

The arrows in this photograph point to **reactive lymphocytes**. Reactive lymphocytes appear in a wide variety of forms, sizes, and shapes. The cytoplasm is light blue, with a deeper blue color at the extreme border. This peripheral basophilia is a characteristic feature of the reactive lymph. The cytoplasmic edge of the reactive lymph tends to flow around adjacent red blood cells. The nucleus is large and elongated or stretched, with coarse chromatin. These lymphocytes are responding to immune stimuli in the body. Other reactive changes in lymphocyte morphology include lower nucleus-to-cytoplasm ratio and the possible presence of nucleoli. Some participants incorrectly identified this cell as a monocyte. Monocytes tend to have folded nuclei and grayer cytoplasm, with pseudopods that appear to push away adjacent red cells. To view another photo of a reactive lymphocyte, see 2019 M2 Specimen BC-8. To view a monocyte, see 2020 M3 BC-14.

BLOOD CELL IDENTIFICATION

Specimen BC-11

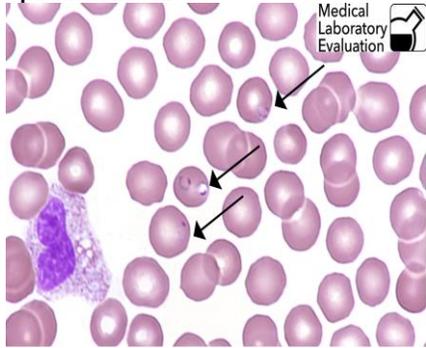

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Macrocyte	88	67.69%	Acceptable
Polychromatophilic red cell	40	30.77%	

The arrows in this photograph point to round **macrocytes**. Macrocytes are abnormally large red blood cells. Normal red blood cells are about the same size as the nucleus of a small normal lymphocyte. The arrowed cells above are slightly larger than the lymphocyte in the same field. As a “rule of thumb”, the nucleus of a mature resting (non-reactive) lymphocyte can be used to provide a relative measurement of the size of the surrounding red blood cells. Macrocytes occur in either oval or round forms. The round form of macrocyte is seen in a variety of chronic illnesses, and target cell-like round macrocytes are a characteristic finding in liver disease. The oval form is associated with vitamin B12 and folate deficiencies, alcoholism, chronic infection, and toxicity. Some participants incorrectly reported these as polychromatophilic red cells. The upper arrowed cell is normochromic, and although the lower arrowed cell is slightly polychromatophilic, its size is greater than a typical polychromatophilic red cell. Therefore, the more specific and correct response is macrocyte. *Technical tip:* When evaluating a smear for red cell morphology, a single finding such as a polychromatophilic cell would not be sufficient for comment on a patient report. The single event would be an indicator to continue scanning the smear for the presence of a population of abnormal cells, which would require a comment on the report.

To view a photo of polychromatophilic red cells see 2020 M2 BC-8. To view another photo of a round macrocyte, see 2016 M2 BC-8. To view a photo of oval macrocytes, see 2018 M1 BC-2. This challenge was graded by referee consensus.

BLOOD CELL IDENTIFICATION

Specimen BC-12

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Malaria	70	53.85%	Educational challenge
Immature/abnormal cell – refer	56	43.08%	
Protozoan, non-malarial	4	3.08%	

The arrows in this ungraded educational challenge point to **malaria** parasites. There are five species of the genus Plasmodium that cause malaria in humans (*P. vivax*, *P. falciparum*, *P. malariae*, *P. ovale* and *P. knowlesi*). Each species has a specific incubation period. The tiny ring forms inside the cells are the trophozoite stage, and are the most common form of the malaria life cycle seen in peripheral blood. To view another photo of malaria, see 2017 M3 Specimen BC-18.

2022 M2

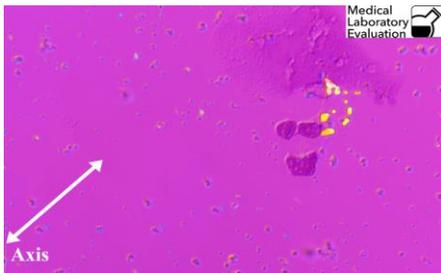

FLUID CRYSTAL IDENTIFICATION

Specimens FC-3 and FC-4

Crystals can generally be classified as either optically isotropic or anisotropic. Isotropic solids refract light rays equally in all directions throughout the crystalline structure, regardless of the crystal's orientation to the light source. In contrast, anisotropic crystals interact with light in a manner that is dependent upon the alignment of the crystal. Anisotropic crystals have internal structure that will cause a ray of light to split into two rays, each traveling in a different direction. A light beam hitting the crystal from one direction or angle will react differently than a beam hitting the crystal at a different angle. This property of splitting light is called **birefringence** or double refraction.

Microscopic examination of synovial fluid for crystals is an important diagnostic test in the evaluation of arthritis. Some crystals can be identified in a wet mount by their shape or morphology alone. Others have similar shapes and need specialized techniques for identification. Using compensated polarized light helps us to identify crystals based on the optical differences described above. Adding a red compensator filter separates the microscope's light rays into slow-moving and fast-moving vibrations or waves. The compensator is marked with an arrow indicating the direction of the slow vibration. The "axis" in the photos below indicates the direction of the slow wave. The color produced by a crystal aligned with the slow-vibration ray of light can be used to identify the crystal. This difference in color is due to the molecular structure inside the crystal, which either allows the light to pass through unchanged, or impedes the light. A **negatively** birefringent crystal such as MSU will appear yellow when aligned with the axis and blue when perpendicular to the axis. Conversely, a **positively** birefringent crystal such as CPPD will appear blue when aligned with the axis and yellow when perpendicular.

Specimen FC-3

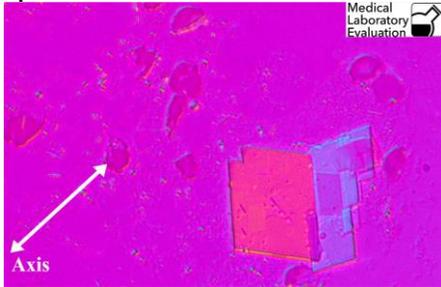

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
No crystals observed	5	100%	Acceptable

There are **no crystals present** in this photograph of a synovial fluid preparation. The brightly colored objects are artefacts/debris. There is one degenerated polymorphonuclear white blood cell present.

2022 M2
FLUID CRYSTAL IDENTIFICATION

Specimen FC-4

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Cholesterol crystals	5	100%	Acceptable

The objects in this photograph are **cholesterol crystals**. The characteristic form of large, flat rectangular plates with notched corners makes them easy to identify in any preparation. Cholesterol crystals may be seen in chronic effusions from patients with osteoarthritis or rheumatoid arthritis. They are associated with chronic inflammatory conditions, but are considered to be a nonspecific finding. To view a photo of cholesterol crystals under normal brightfield illumination, see 2019 M1 Specimen FC-1. To view another photo of cholesterol under polarized, red compensated light, see 2020 M1 Specimen FC-2

KOH SKIN PREPARATION

Technical note: 10-20% KOH is a suitable concentration for KOH preparations. The recommended wait time for read is up to 30 minutes to allow cellular tissue and debris to dissolve. Alternatively, the slide may be heated using a heating block. Follow your laboratory specific protocol for KOH concentrations and wait times.

2022 M2**Urine Sediment Identification****SPECIMENS US-3 AND US-4**

CASE HISTORY:

A 57-year-old female was referred to a urology clinic for evaluation due to recurring urinary tract infections. She was treated three times in the last 6 months by her family physician, but after the antibiotics were stopped her symptoms returned. At her last visit a urine culture was performed and grew > 100,000 cfu/mL *Klebsiella pneumoniae*. She is currently asymptomatic, not taking any medication, and her physical examination is unremarkable. Kidney ultrasound was performed which revealed a 1.1-cm irregularly shaped stone in the right renal pelvis. A clean catch urine was collected, and the urinalysis results appear below.

Color= Yellow

Appearance= Cloudy

DIPSTICK RESULTS:

Specific gravity = 1.025

pH = 8.5

Protein = Negative

Glucose = Negative/Normal

Ketones = Negative

Bilirubin = Negative

Urobilinogen = Normal/0.2 mg/dL

Blood = Small (1+)

Leukocyte Esterase = Small (1+)

Nitrite = Negative

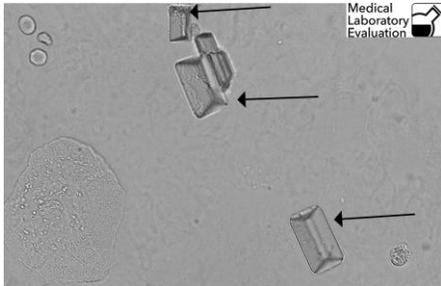

This patient was diagnosed with nephrolithiasis (kidney stones.)

Crystalline stones, also called calculi, may form in the urinary tract from materials that are normally excreted in the urine. Although stones can form anywhere along the urinary tract, the most common site is in the kidney. The terms *nephrolithiasis* and *renal calculi* refer specifically to the presence of stones inside the kidneys. Small calculi may be passed from the kidney into the urine, causing severe pain radiating from the lower back to the legs. Larger calculi cannot be passed and may remain undetected until the patient develops symptoms of urinary obstruction. Recommended management for a patient having an acute stone event is NSAIDs for pain control, and relaxation. Increasing fluid intake causes more discomfort and does not help the stone to pass.

Some people are more likely to develop certain types of kidney stones based on their diet and family history. The major types of stones include: calcium oxalate, calcium phosphate, struvite (aka, triple phosphate), uric acid, and cystine stones. The primary laboratory finding is hematuria (either gross or microscopic) resulting from irritation to the tissues by the moving stone. However, the absence of hematuria does not rule out urinary stone disease. Urinary pH can give the provider a clue to the stone composition, with a very low pH suggesting uric acid stones, or at the other end, a very high pH could indicate struvite stones. Crystals that contribute to the stone formation may or may not be present in the urine sediment.

Urine Sediment Identification

Specimen US-3

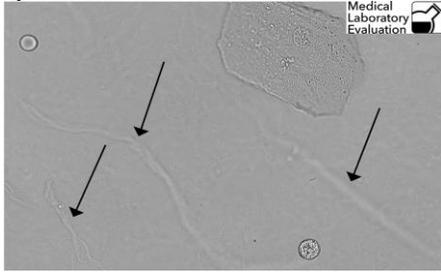

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Triple phosphate crystal	301	97.41%	Acceptable

The arrows in this photograph point to **triple phosphate crystals**. The typical 3-6 sided rectangular shape is described as a “coffin lid”. They can vary greatly in size, and are commonly seen in neutral or alkaline urine (pH \geq 7.0). These crystals are rarely clinically significant, however triple phosphate (also called struvite) can be a major component of urinary stones in the kidneys. Struvite calculi are closely related to urinary tract infections (UTI); hence they are also known as infection stones. Infection or colonization by urease-producing organisms like *Proteus*, *Klebsiella*, *Staphylococcus*, *Pseudomonas*, *Providencia*, *Serratia*, and *Morganella* can cause struvite stones. These stones tend to grow quickly and become large, sometimes occupying the entire renal pelvis. Left untreated, the stones can cause frequent and severe urinary tract infections and loss of kidney function. To view another photo of triple phosphate crystals, see 2017 M1 Specimen US-2.

Urine Sediment Identification

Specimen US-4

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Mucus strands	287	92.88%	Acceptable
Fiber/fecal contamination	11	3.56%	
Yeast/fungi	6	1.94%	

The arrows in this photograph point to **mucus strands**. Mucus is a normal secretion of glands in the urethra and vagina. It is a common non-pathologic finding, especially in females. Mucus appears as long delicate strands or threads with undefined edges and pointed or frayed ends. Mucus can be mistaken for hyaline casts because of their similar low refractive index. However, hyaline casts have definite edges and smooth ends. To view a hyaline cast, see 2014 M1 Specimen US-2. To view another photo of mucus, see 2019 M3 Specimen US-6.

Technical tip: Objects with low refractive index, like mucus and hyaline casts, are hard to see if the microscope's illumination is not set correctly. Use subdued lighting to examine urine sediment, with the sub-stage condenser raised all the way up, and the condenser iris diaphragm approximately 70% closed / 30% open. Do not lower the condenser to decrease brightness. This reduces the resolution and sharpness of the image, which could cause you to miss important elements like casts.

 PROVIDER-PERFORMED MICROSCOPY (PPM)
 Specimens PPM-7 through PPM-12

WET MOUNT PREPARATION

Specimen PPM-7

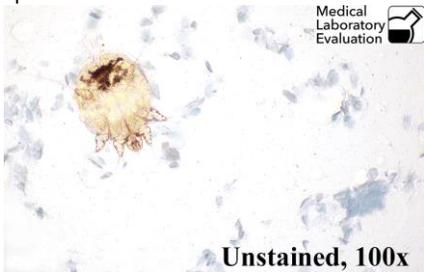

Unstained, 400x

The arrows in this photograph of a vaginal wet mount point to *Trichomonas vaginalis*. *T. vaginalis* is a single-celled protozoan parasite that is about the same size as a white blood cell. It can be pear-shaped, rounded, or triangular. It has four flagella, an anterior undulating membrane, and a sharp protruding posterior axostyle that looks like a tail. Trichomonas is easily identified in a fresh wet prep by its distinctive irregular, jerky, rotating motility. Trichomoniasis is a common sexually-transmitted infection (STI) that affects women more often than men, and is easily cured with medication. Symptoms include urinary frequency, burning and discharge. The genital inflammation caused by Trichomonas can make the patient more susceptible to other STIs such as HIV. To view another photo of Trichomonas, see 2019 M1 Specimen PPM-1.

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Trichomonas vaginalis	353	98.33%	Acceptable

SCABIES DETECTION

Specimen PPM-8

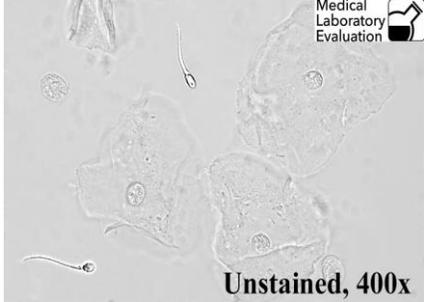

Unstained, 100x

A scabies mite is present in this photograph of a skin scrapings preparation. The scabies mite, or human itch mite (*Sarcoptes scabiei*), is usually spread by prolonged direct personal contact with an infested person. It can also be spread indirectly by prolonged contact with infested clothing or bedding. The mites burrow into the skin and produce an itchy papular (pimple-like) rash. The diagnosis of scabies is often made only by the patient history and examination of the skin. Identification of the mite, its burrows, eggs, or feces (called scybala) confirms the clinical suspicion of scabies. Scabies can be difficult to find by laboratory testing, though, because mites are often few in number. There may be only 10-15 mites on the entire body of an infested person who is otherwise healthy, so a negative test does not rule out the diagnosis. To view another photo of a scabies mite, see 2017 M1 Specimen PPM-3.

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Scabies present	144	100%	Acceptable

SPERM DETECTION

Specimen PPM-9

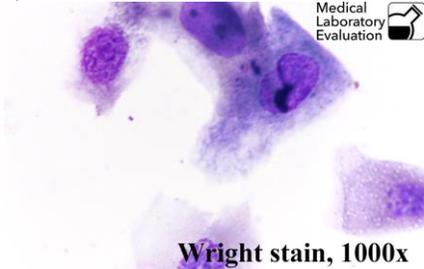

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Sperm present	190	100%	Acceptable

Two spermatozoa are present in this photograph of a vaginal wet mount preparation.

PROVIDER-PERFORMED MICROSCOPY (PPM)

NASAL SMEAR

Specimen PPM-10

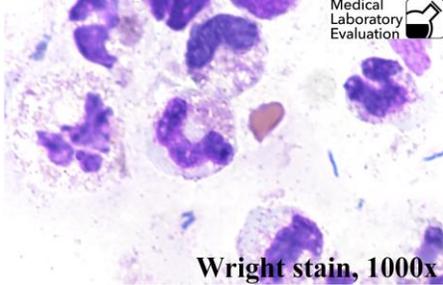

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Eosinophils absent	35	74.47%	Acceptable
Eosinophils present	12	25.53%	

Eosinophils are absent in this photograph of Wright-stained nasal mucus. The cytoplasm of an eosinophil is filled with large, round, red-orange granules that surround a segmented, purple nucleus. The cells shown in this photo are not orange, therefore they are not eosinophilic. The orange color of the eosinophil comes from the dye eosin, which is a component of Wright stain. The purpose of examining respiratory secretions for leukocytes (white blood cells) is to differentiate allergic conditions from infections. Eosinophils are a specific type of leukocyte associated with allergic conditions. The unique red-orange color of "Eos" makes them easy to spot and identify. To view a photo of eosinophils in a nasal smear, see 2019 M3 Specimen PPM-16. This challenge was graded by referee consensus.

STOOL PREPARATION

Specimen PPM-11

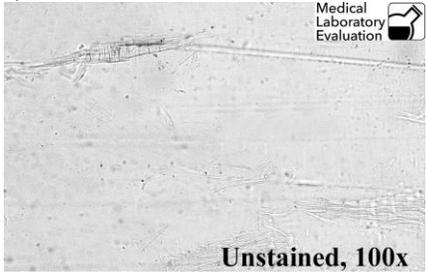

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Leukocytes present	121	100%	Acceptable

Leukocytes are present in this photograph of a Wright stained stool preparation. To view another photo of fecal leukocytes, see 2019 M2 Specimen PPM-11.

PINWORM PREPARATION

Specimen PPM-12

<u>Identification</u>	<u>Labs</u>	<u>Percent</u>	<u>Performance</u>
Pinworms/eggs absent	138	97.18%	Acceptable
Pinworms/eggs present	4	2.82%	

Pinworms/eggs are absent in this photograph of a perianal pinworm preparation. To view a photo of pinworm eggs, see 2021 M2 Specimen PPM-12.
